A function $f$ is called continuous at a point $p$ if a value $f(p)$ can be found such that $f(x) \to f(p)$ for $x \to p$. A function $f$ is called continuous on $[a, b]$ if it is continuous for every point $x$ in the interval $[a, b]$.

In the interior $(a, b)$, the limit needs to exist both from the right and from the left. At the boundary $a$ only the right limit needs to exist and at $b$ only the left limit. Intuitively, a function is continuous if you can draw the graph of the function without lifting the pencil. Continuity means that small changes in $x$ results in small changes of $f(x)$.

1. Any polynomial is continuous everywhere. To see this note that the sum of two continuous functions is continuous and that a multiple of a continuous function is continuous. Since $x^n$ is continuous for all $n$, and every polynomial is a sum of multiples of such functions, we have continuity in general.

2. The function $f(x) = 1/x$ is continuous everywhere except at $x = 0$. It is a prototype of a function which is not continuous due to a pole. The source for the trouble is the division by zero which would happen if we would try to evaluate the function at $x = 0$.

3. The function $\csc(x) = 1/\sin(x)$ is not continuous at $x = 0, x = \pi, x = 2\pi$ and any multiple of $\pi$. It has poles there because $\sin(x)$ is zero there and because we would divide by zero at such points.

4. The function $f(x) = \sin(\pi/x)$ is continuous everywhere except at $x = 0$. It is a prototype of a function which is not continuous due to oscillation. We can approach $x = 0$ in ways that $f(x_n) = 1$ and such that $f(z_n) = -1$. Just chose $x_n = 2/(4k+1)$ and $z_n = 2/(4k-1)$.

5. The signum function $f(x) = \text{sign}(x) = \begin{cases} 1 & x > 0 \\ -1 & x < 0 \\ 0 & x = 0 \end{cases}$ is not continuous at 0. It is a prototype of a function which has a jump discontinuity at 0.

We can refine the notion of continuity and say that a function is continuous from the right, if there exists a limit from the right $\lim_{x \to a} f(x) = b$. Similarly a function $f$ can be continuous from the left only. Most of the time we mean with "continuous"= "continuous on the real line".

Rules:

a) If $f$ and $g$ are continuous, then $f + g$ is continuous.

b) If $f$ and $g$ are continuous, then $f \cdot g$ is continuous.

c) If $f$ and $g$ are continuous and if $g > 0$ then $f/g$ is continuous.

d) If $f$ and $g$ are continuous, then $f \circ g$ is continuous.

6. $\sqrt{x^2 + 1}$ is continuous everywhere on the real line.
7 \cos(x) + \sin(x) \text{ is continuous everywhere.}

8 The function \( f(x) = \log(|x|) \) is continuous everywhere except at 0. Indeed since for every integer \( n \), we have \( f(e^{-n}) = -n \), this can become arbitrarily large for \( n \to \infty \) even so \( e^{-n} \) converges to 0 for \( n \) running to infinity.

9 While \( \log(|x|) \) is not continuous at \( x = 0 \), the function \( 1/\log|x| \) is continuous at \( x = 0 \). Is it continuous everywhere?

10 The function \( f(x) = [\sin(x + h) - \sin(x)]/h \) is continuous for every \( h > 0 \). We will see next week that nothing bad happens when \( h \) becomes smaller and smaller and that the continuity will not deteriorate. Indeed, we will see that we get closer and closer to the \( \cos \) function.

There are three major reasons, why a function is not continuous at a point: it can \textbf{jump}, \textbf{oscillate} or \textbf{escape} to infinity. Here are the prototype examples. We will look at more during the lecture.

Why do we like continuity? We will see many reasons during this course but for now let's just say that:

A wild continuous function. This Weierstrass function is believed to be a fractal.

"Continuity tames a function. It can be pretty wild, but not too crazy."

A crazy discontinuous function. It is discontinuous at every point and known to be a fractal.
Continuity will be useful later for extremization. A continuous function on an interval \([a, b]\) has a maximum and minimum. And if a continuous function is negative at some place and positive at an other, there is a point between, where it is zero. These are all useful properties to have and they do not hold if a function is not continuous.

Problem Determine from each of the following functions, where discontinuities appear and give a short reason.

\(a\) \(f(x) = \log(|x^2 - 1|)\)
\(b\) \(f(x) = \sin(\cos(\pi/x))\)
\(c\) \(f(x) = \cot(x) + \tan(x) + x^4\)
\(d\) \(f(x) = x^4 + 5x^2 - 3x + 4\)
\(e\) \(f(x) = \frac{x^2 - x}{x}\)

Solution.

\(a\) \(\log(|x|)\) is continuous everywhere except at \(x = 0\). Since \(x^2 - 1 = 0\) for \(x = 1\) or \(x = -1\), the function \(f(x)\) is continuous everywhere except at \(x = 1\) and \(x = -1\).

\(b\) The function \(\pi/x\) is continuous everywhere except at \(x = 0\). Therefore \(\cos(\cos(\pi/x))\) is continuous everywhere except possibly at \(x = 0\). We have still to investigate the point \(x = 0\) but there, the function \(\cos(\pi/x)\) takes values between \(-1\) and \(1\) for points arbitrarily close to \(x = 0\). The function \(f(x)\) takes values between \(\sin(-1)\) and \(\sin(1)\) arbitrarily close to \(x = 0\). It is not continuous there.

\(c\) The function \(x^4\) is continuous everywhere. We do not have to consider it. The function \(\tan(x)\) is continuous everywhere except at the points \(k\pi\), integer multiples of \(\pi\). The function \(\cot(x)\) is continuous everywhere except at points \(\pi/2 + k\pi\). The function \(f\) is therefore continuous everywhere except at the point \(x = k\pi/2\), multiples of \(\pi/2\).

\(d\) The function is a polynomial. We know that polynomials are continuous everywhere.

\(e\) The function is continuous everywhere except at \(x = 0\), where we have to look at the function more closely. But we can heal the function by dividing nominator and denominator by \(x\) which is possible for \(x\) different from 0. We get \(x - 1\).

Homework

1 On which intervals is the following function continuous?
Solution:
The function has a jump discontinuity at 5 and goes to infinity at \( x = 0 \). There is discontinuity at \( x = 3 \). The function is continuous on \( (-\infty, 0), (0, 5), (5, \infty) \).

2  For the following functions, determine the points, where \( f \) is not continuous.
   a) \( f(x) = \tan(1 - x) \)
   b) \( x \cos(1/x) \)
   c) \( \text{sign}(x)/x \)
   d) \( \text{sinc}(x) + \sin(x) + x^8 + \log(x) \)
   e) \( \frac{x^2 + 5x + x^4}{x-1} \)

State which kind of discontinuity appears.

Solution:
   a) \( x = \pi/2 + 1 \).
   b) This is continuous everywhere. The only point to check is \( x = 0 \) where the function is not defined at first.
   c) This function is not defined at \( x = 0 \) at first. We can define \( f(0) = 0 \) and get a continuous function.
   d) This function has a pole at \( x = 1 \). There is no way we can fix the discontinuity at this point.

3  Construct a function which has a jump discontinuity, an oscillatory one as well as an escape to infinity. Can you construct an example where two of these flaws happen at the same point? Can you even construct an example where all three happen at the same point?

Solution:
   a) \( \sin(1/x) + \sin(x - 1)/|x - 1| + 1/(x - 2) \) is an example.  
   b) The discontinuity in Problem 1) at \( x = 0 \) can be considered an example where jump and infinity comes together. The case \( f(x) = x \sin(x) \) would produce oscillatory and ifinity. A case like \( \sin(1/x) + 5 \sin(x)/|x| \) would produce a jump and oscillatory discontinuity at both points. It is difficult to combine all three together.

4  Heal the following functions:
   a) \( (x^5 - 32)/(x - 2) \)
   b) \( x^5 - x^3/(x^2 - 1) \)
   c) \( ((\sin(x))^3 - \sin(x))/\sin(x) \).
   d) \( (x^3 + 3x^2 + 3x + 1)/(x^2 + 2x + 1) \)
   e) \( (x^{1000} - 1)/(x^{100} - 1) \)
Solution:

a) $x^4 + 2x^3 + 4x^2 + 8x + 16$.

b) $x^2$.

c) $\sin(x)^2 - 1$.

d) Call $y = x^{100}$ then we have $(y^{10} - 1)/(y - 1) = 1 + y + y^2 + y^3 + ... + y^9$. This is $1 + x^{100} + ... + x^{900}$.

5. Is the following function continuous?

$$\frac{\cos(\cos(\cos(\cos(x))))}{\sin(\sin(\sin(\sin(\sin(e(e(e(e(e(e(x)))))\)))\)))}}$$

$$\log(2x+1)+2+\cos((x))$$

Solution:

But in any case, the function is not continuous. The function is of the form $A/(B/C) = AC/B$. For $x = -1/2$, we hit the logarithmic singularity. If you read it as $(A/B)/C$,

then there is a problem where $\sin(\sin(\sin(\sin(e(e(e(e(e(e(x)))))\)))\))) = 0$. And there is a point $x$, where $e(e(e(e(e(e(x)))))\))) = \pi$.
